INTRODUCTION

Coal mining has been conducted in western Pennsylvania, as well as much of the Appalachian Coal Basin, for more than 150 years. With Pennsylvania's coal reserves playing a major role in the Industrial Revolution, the United States became a modern developed nation and major world power. This historical utilization of coal to heat our homes and to fuel our industries, however, resulted in a legacy of severe environmental impacts and public safety issues. The majority of these impacts are associated with mines operational prior to the federal Surface Mining Control and Reclamation Act of 1977 and Pennsylvania's legislative efforts including the Surface Mining Conservation and Reclamation Act of 1945.

Small towns and villages of western Pennsylvania and Appalachia, which were once bustling coal communities supporting the steel industry and electricity generation for such cities as Pittsburgh (PA), Wheeling (WV), and Johnstown (PA), are now often non-existent ghost towns left with only scarred landscapes characterized by dangerous highwalls, barren coal refuse piles, and, polluted mine drainage. According to the Pennsylvania Integrated Water Quality Monitoring and Assessment Report (PA DEP, 2006), these pollutive discharges, commonly referred to as abandoned mine drainage (AMD), are the largest source of stream degradation in the Commonwealth, with over 4,600 miles of streams impacted. Furthermore, 45 of Pennsylvania's 67 counties are impacted with over 250,000 acres of unreclaimed mine lands, 2.6 billion cubic yards of abandoned coal refuse, and about 7,800 abandoned underground mines. In many cases, entire watersheds have been completely decimated by AMD.

Since 1994, the Slippery Rock Watershed Coalition (SRWC) has been actively working to restore the severely degraded headwaters of Slippery Rock Creek. This effort has resulted in the installation of about 18 passive systems for approximately 30 abandoned mine discharges. These passive systems are currently treating over 750 million gallons of mine drainage per year eliminating about 200 tons of iron, 8 tons of aluminum, and 335 tons of acidity annually from Slippery Rock Creek and its tributaries. This reduction in pollution loading has significantly improved over 11 miles of streams with fish being observed in at least 6 miles of streams for the first time in over a century.

Much of the work completed by the SRWC to date has been based upon background data collected by the Pennsylvania Department of Environmental Protection (PA DEP) Knox District Mining Office (Knox DMO) as published in the 1998 Slippery Rock Creek Watershed Comprehensive Mining Reclamation Strategy (CMRS) Reclamation/Remediation Plan (for a 27-square mile area of the headwaters. While Blacks Creek, a major tributary in the headwaters of Slippery Rock Creek, was not included in the CMRS, a Total Maximum Daily Load (TMDL) was prepared by the Knox DMO (PA DEP, 10/20/04) and approved by the US Environmental Protection Agency (US EPA) on 01/19/05. In 2005, Stream Restoration Incorporated was awarded a US EPA 319 grant to address the BC16 abandoned mine discharge located along an unnamed tributary to Blacks Creek. Prior to utilizing these funds for construction, a watershed restoration plan was needed to provide an overview of Blacks Creek and tributaries thereto in relation to the applicable water quality criteria cited in the TMDL as well as to identify sources of degraded mine drainage. The sources were also characterized and prioritized based on pollutant loading and impact to the overall watershed. Best Management Practices (BMP), such as land reclamation and passive treatment systems, with rough cost estimates, were also described.

BLACKS CREEK WATERSHED DESCRIPTION & CHARACTERISTICS

Blacks Creek (DEP Stream Code 34731, Basin 20-C) is a major headwaters tributary and subwatershed of Slippery Rock Creek in the Ohio River Basin in western Pennsylvania. (The attached Stream Map identifies the Reach Codes from the National Hydrography Dataset developed by the USGS and EPA.) The Blacks Creek Watershed is primarily located in Marion and Venango Townships in northern Butler County with a small portion located in Irwin and Clinton Townships in southern Venango County. (See Topographic Map.) The watershed encompasses approximately 9-square miles (5,600 acres) with approximately 110,000 feet (20.8 miles) of 1st, 2nd, 3rd, and 4th order streams that flow in a generally southern direction. The Blacks Creek headwaters are characterized by spring/wetland- and abandoned mine discharge-fed tributaries. Blacks Creek enters Slippery Rock Creek about a mile west of Boyers, PA.

Surface elevations range from about 1200 to 1600 feet and contain, relatively flat, rural and forested lands with gently rolling hills of low relief. A stream gradient analysis was completed on the major tributaries of Blacks Creek by utilizing streams digitized from aerial photography (1' resolution) and a digital terrain model generated from USGS contours (20' intervals). The analysis is presented in Table I as well as on the attached Stream Gradient Map. As shown, over 70% of Blacks Creek and the major tributary (Trib 6 on the Blacks Creek Watershed Map) are considered low or very low gradient.

Table I. Stream Gradient Analysis

Gradient (% slope)	Classification	Length		Percent
		Feet	Miles	
0-0.99	very low	25275.4	4.79	38.5
1-1.99	low	20997.5	3.98	32.0
2-3.99	moderate	11483.0	2.17	17.5
4-7.99	high	6561.9	1.24	10.0
8-20	very high	1312.3	0.25	2.0
Total		65630.1	12.43	100.0

The Blacks Creek Watershed has been extensively mined through both surface and underground methods primarily on the Middle Kittanning, Lower Kittanning, and Brookville coalbeds. Numerous abandoned mine features such as spoil piles, coal refuse piles, water-filled surface mine pits, dangerous highwalls, subsidence, and abandoned mine drainage can be seen throughout the watershed as well as successfully-reclaimed surface mines. While there are currently two active quarries on the Vanport limestone that may be removing incidental coal encountered, there are no coal mines currently in operation within the watershed. In addition to mining, the northern part of the watershed is part of the Bullion-Clintonville Oil Field, with average pay zones at a depth of about 1050 feet in the Venango Second and Third Sandstones. Petroleum exploration was reported to have begun around 1876. Numerous historic, as well as more recent, oil wells, pumping facilities, storage tanks, and piping systems are commonly observed in this portion of the watershed.

Major land uses in the Blacks Creek Watershed were documented in the Slippery Rock Creek Watershed Assessment and Restoration Plan (Beran et al, 2006) utilizing digital, orthophoto, quarter-quadrangle, aerial photographs (1993-1995) developed and published by the USGS. (See Table II.)

Table II. Land Uses in the Blacks Creek Watershed

WATER QUALITY

Sources of Data

Several sources of data were used to develop the restoration plan. A large portion of the data was obtained from the PA DEP Knox DMO. Other sources of data included Non-Coal Surface Mining Permits 10960301 and 10960302 for limestone quarries operated by Quality Aggregates Inc. and Allegheny Mineral Corporation, respectively, and previous restoration activities including Operation Scarlift (Gwin, 1970) and the Slippery Rock Creek Watershed Assessment and Restoration Plan (Beran et al, 2006). In addition, BioMost, Inc. collected samples both as part of developing this restoration plan as well as part of other remediation efforts.

The use of numerous sources created a significant data management challenge with many sampling locations having multiple sample names and nomenclature systems. For example, BC8, BC2, and 906-32 of the PA DEP, Beran Environmental, and BioMost, Inc., respectively, were for the same sampling location. In addition, this point was approximately the same as Allegheny Mineral sampling point 40K. After all known available data were obtained and entered into the water quality database, there were nearly 150 named sampling points. For purposes of simplifying data management, sample point locations that were similar, but with different names, were combined and renamed when necessary to provide only one designation for any given sample point location. Table III provides a key to sample point locations with multiple names. Sample points with only one name were not included in the table. Sample point locations are identified on the Blacks Creek Watershed Map.

Water Quality Criteria

In this area, PA Title 25, Chapter 93 (electronically retrieved 01/31/07), designates Slippery Rock Creek and the tributaries thereto as a Cold Water Fishery with the following water quality criteria:

- Alkalinity - Min. 20 mg/L as CaCO₃, except where natural conditions are less...
- Dissolved Oxygen - For flowing waters, min. daily average 6.0mg/l...
- Iron - 30-day avg. 1.5 mg/L as total recoverable
- Osmotic Pressure - Max. 50 milliosmoles/kg
- pH - From 6.0 to 9.0 inclusive
- Total Dissolved Solids - 500 mg/L as a monthly avg. value; max. 750 mg/L

The TMDL documented that Blacks Creek was impaired with respect to metals from abandoned mine drainage, in agreement with the 2002 PA Section 303(d) list and the 2006 PA Integrated Water Quality Monitoring and Assessment Report.

Table IIIa. Blacks Creek TMDL Stream Identification

Year	Miles	Seg. ID	DEP Stream Code	Stream Name	Designated Use	Data Source	Source	EPA 305(b) Cause Code
2002	4.6	4570	34731	Blacks Creek	CWF	SWMP	AMD	Metals

Portion of Table 1. 303(d) Sub-List; State Water Plan (SWP) Subbasin: 20-C Slippery Rock Creek Watershed in Final Blacks Creek Watershed TMDL Butler County (10/20/04), EPA approved 01/19/05; Cold Water Fishes (CWF); Surface Water Monitoring Program (SWMP)

Note that the applicable water quality criteria listed in the TMDL (See Table IV.) does not correspond with that listed in Chapter 93. For instance, Subchapter 93.7 reserves the total manganese and dissolved iron criterion values for streams designated with the critical use as a Public Water Supply. For the purpose of this report, stream quality was not compared to Chapter 93 criteria. The applicable water quality criteria listed in the TMDL are to be met 99% of the time. (See Table IV.)

Table IV. TMDL Applicable Water Quality Criteria

Parameter	Criterion Value
Aluminum - Total	0.75 mg/L
Iron - Total	1.50 mg/L
Iron - Dissolved	0.3 mg/L
Manganese - Total	1.00 mg/L
pH	6.0 – 9.0 standard units

Since the primary cause of impairment to Blacks Creek is metals associated with mine drainage, decreasing the iron, aluminum, and manganese concentrations within the streams to meet the applicable water quality criteria identified in the TMDL report are the ultimate goal of this restoration plan. The average values at sample point locations were used for comparison to TMDL criteria. In instances where only one sample was collected for a given point, the single set of analyses was assumed to represent the average water quality at that location. (Please note that continued monitoring may reflect a significantly different average water quality.)

Discussion of Stream Water Quality

Table V characterizes the unnamed tributaries to Blacks Creek. (The attached Stream Map provides a key to both the Reach Codes and the “trib #”.) “Trib #” is used within the narrative and shown on the Blacks Creek Watershed Map with sample point locations.

Data were compiled or collected for every unnamed tributary, except tributaries #3 and #4. Tributary #3 was not sampled due to accessibility, but is assumed to be of good quality based upon water quality characteristics of similar tributaries in the watershed which have little or no mining in the contributory drainage area. Tributary #4 was also not sampled; however, a pH of 6.5 was measured on 10-03-06. As there was minimal flow at this location and mining was not indicated on the 7½’ USGS topographic map in the contributory drainage area, a sample was not collected for laboratory analysis.

Except for a few segments, most of Blacks Creek and its tributaries have an acceptable pH and are net alkaline. This is assumed to be largely due to the influence of the persistent Vanport limestone (typically, 90% calcium carbonate content) which is <50 feet stratigraphically below the Lower Kittanning coalbed and crops out in the area. Of the 19 unnamed tributaries to Blacks Creek, 13 met all of the water quality criteria identified in Table IV.

Tributaries Not Meeting Applicable Water Quality Criteria (TMDL)

Tributary #6 meets the criteria for most of its length, except for the iron content at 906-24, which is the effluent from an in-stream, settling pond on a reclaimed surface mine within the headwaters. The pond discharge meets the surface mining permit effluent limit for total iron, which is 7 mg/L. Downstream the water becomes oxygenated, mixes with other sources, and the Table IV criteria are met at point 906-27.

Tributary #8 meets the criteria except for very slightly exceeding the dissolved iron content at point 906-25. With only one sample analysis, additional monitoring would be necessary to determine if the dissolved iron content is of concern. Further downstream at point 906-28, tributary #8 meets all criteria.

Tributary #7 is formed by the confluence of two small abandoned mine discharges (906-22 and 906-23), which as noted in Table V, are only slightly impacted. These discharges meet the typical surface mine permit effluent limits. Tributary #7 receives additional base flow and mixes with other water sources and, at downstream point 906-19, all criteria are met except for slightly exceeding the dissolved iron criterion of 0.3 mg/L. This may be due to a small abandoned mine discharge (906-21) that enters the tributary about 50 feet upstream of point 906-19.

Tributary #15, also referred to as the "McIntire trib", is the most degraded tributary and is responsible for the majority of the metal loading to Blacks Creek. As shown in Table V, there is not a single sampling point along the tributary that meets the water quality criteria identified in Table IV. This tributary is primarily impacted by two sources of mine drainage. The first source is a bond forfeiture site known as the "McIntire" minesite, which is located at the headwaters of the tributary. Mine discharges MC1, MC2, and MC3 enter an existing chemical treatment pond (TB1), which is no longer in operation. The effluent of TB1 essentially forms tributary #15. As this water travels downstream, a combination of natural processes and dilution from base flow and other sources of water improve the quality of the stream, but as noted at downstream point BC4.1, the stream remains heavily impacted. A second discharge, BC16, an upwelling of mine drainage from an abandoned oil well, enters tributary #15 between BC4.1 and the final downstream point BC4, located at the mouth of tributary #15 prior to the confluence with Blacks Creek. As noted in Table V, tributary #15 at BC4 is still heavily impacted. The impact of the "McIntire trib" to Blacks Creek is severe as observed by the change in water quality (Table VI) upstream (906-42) and downstream (BC2) of the confluence with tributary #15.

Tributary #16 is essentially formed by the effluent of a sediment pond (906-16) at an old reclaimed surface mine. The sediment pond receives both good quality surface runoff collected by diversion ditches, as well as poor quality mine drainage (906-17 & 906-17b) that flows onto and across the reclaimed surface mine. Mine discharge point 906-16 exceeds the total manganese and aluminum criteria as well as the dissolved iron and pH criteria. The drainage mixes with good quality water downstream, significantly improves, and, based upon data collected by PA DEP, tributary #16 meets the water quality criteria at the mouth (BC5) prior to the confluence with Blacks Creek.

Tributary #18, formed by two abandoned mine discharges (906-4 & 906-5), was sampled at point B-BC7.2B. Downstream from this point, the flow mixes with other sources of water of varying quality within a large wetland complex.

Tributary #19 is also formed by abandoned mine discharges (906-7, -8, -9) and sources of good quality water. These discharges mix within a wetland created by a beaver dam. Below the beaver dam, at point 906-6, the applicable water quality criteria are met, except for manganese.

Table V. Unnamed Tributaries Water Quality Data (Average Values)

Trib # corresponds to the tributary number provided on the Stream Map; pH in standard units; Alkalinity, acidity, total and dissolved metals, and sulfates in mg/L; Metals and pH rounded to nearest tenth; Alkalinity, acidity, and sulfates rounded to nearest whole number; Highlighted entries indicate the unnamed tributary, sampling point, and parameter which do not meet the applicable water quality criteria (TMDL) listed in Table IV. Dissolved manganese and aluminum are also highlighted if the total concentrations exceed the applicable water quality criteria (TMDL). (See attached monitoring data.)

Blacks Creek

While the majority of the unnamed tributaries to Blacks Creek met the water quality criteria listed in Table IV, most of the length of Blacks Creek, as identified in Table VI, does not.

Tributaries #18 and #19 appear to confluence within a large wetland complex. The effluent of this wetland forms Blacks Creek and is represented by sample point 906-10 which does not meet the water quality criteria for pH, manganese, and aluminum. At sampling point 906-11,

even though the Blacks Creek water quality has significantly improved due to the influence of good quality springs and seeps, water quality criteria are not met. Below the confluence of tributary #17, Blacks Creek is sampled at 906-15. At 906-15, the manganese and aluminum criteria are exceeded while pH is just slightly below the criterion of 6-9. While good quality water enters and improves Blacks Creek as evidenced by point BC14.1, the stream still exceeds the criteria for manganese and total aluminum. Note, however, that the dissolved aluminum content has decreased below 0.75 mg/L with total aluminum representing mostly particulates which are probably either suspended clay particles or precipitated aluminum solids. The water quality of Blacks Creek would probably continue to improve except for the impacts associated with two upwellings (BC14 & BC15) from abandoned oil wells conveying mine drainage. These discharges severely impact Blacks Creek as noted at point 906-42. While aluminum content has decreased below the applicable water quality criterion, the iron and manganese content has increased. About 75 feet downstream of 906-42, the severely impacted tributary #15 (“McIntire trib”) enters Blacks Creek. The impact of this tributary can be seen 50-100 feet downstream at point BC2 where iron, manganese, and aluminum concentrations have increased. Just downstream of BC2, the effluent of the BC19 & 19B passive treatment system (905-WL) enters Blacks Creek. Prior to installation of the passive system, these two discharges, which emanate from oil wells, directly entered Blacks Creek. Downstream of the passive treatment system at BC2B, there is generally an improvement to the stream, but the criteria are still exceeded for iron, manganese, and aluminum. Further downstream at BC1A, the water quality has improved as the concentration of aluminum no longer exceeds the water quality criterion. At BC1, the stream has improved so that only total iron and manganese criteria are exceeded. Even with the confluence of good quality tributaries #13, #12, and #11, Blacks Creek, on average, still exceeds the iron and manganese criteria at point BC8. While Blacks Creek cannot be shown to meet all of the applicable water quality criteria until sampling point QAS1, more than likely the stream is significantly improved by tributary #6. The furthest downstream sampling point on Blacks Creek is QAS4 near the mouth, just above the confluence with Slippery Rock Creek.

Table VI. Blacks Creek Water Quality Data (Average Values)

	Sample Point	pH field	Alkalinity		Acidity	Iron		Manganese		Aluminum		SO ₄
			field	lab		total	diss.	total	diss.	total	diss.	
			← Downstream	906-10		4.8	2	3	21	0.4	0.3

pH in standard units; Alkalinity, acidity, total & dissolved metals, and sulfates in mg/L; Highlighted or shaded entries indicate the Blacks Creek sampling point and the parameters which do not meet the applicable water quality criteria listed in Table IV. Dissolved Mn and Al are also highlighted if the total concentrations exceed the applicable water quality criteria (TMDL). The parameters analyzed and the sample sets for the individual points vary. (See attached monitoring data.)

Where flow rates were measured, loadings were calculated. Table VII provides a summary of average loading values for each sampling point on Blacks Creek where flow rates were available. The number of flow measurements for each sampling location varied. This inconsistency along with inherent inaccuracy associated with various flow measurement methods, may explain why either BC8 has significantly higher values or BC1 has significantly lower values than expected, compared to other sampling point loadings. As the majority of the significant AMD discharges enter prior to BC2 and as the constituents of interest are not conservative, good quality water from tributaries and/or base flow to Blacks Creek are expected not only to dilute concentrations (no impact to loadings) but also to encourage precipitation of metal solids resulting in decreased loadings. The increase in iron and manganese loadings between BC1 and BC8 for one or both of the sampling point loadings, therefore, is probably inaccurate. Of particular interest is the large increase in metal loading between sampling point 905-15 and BC2. This section of stream is where discharges BC14, BC15 and tributary #15 (conveying mine drainage from the MC1, MC2, MC3, and BC16 discharges) enter Blacks Creek. As will be further discussed in later sections, addressing the discharges in this area of the watershed will be imperative to the restoration of Blacks Creek.

Table VII. Blacks Creek Average Loadings at Selected Sampling Points

Sample Point	Alkalinity	Acidity	Total Fe	Total Mn	Total Al	Total Fe, Mn, Al
906-15	32.2	16.7	0.3	3.4	4.2	7.9
BC2	612.0	-241.6	53.0	31.3	7.8	92.1
BC2B	599.5	-243.6	42.8	29.2	5.2	77.2
BC1	841.9	-151.3	25.1	32.3	1.8	59.2
BC8	1394.8	-215.8	41.7	47.1	1.0	89.8
QAS1	364.6	-178.3	2.6	2.9	1.1	6.6
QAS4	537.3	-226.1	4.4	5.4	1.3	11.1

All loadings in lbs/day based on available laboratory measurements to date. The number of sample sets (n) varies. (See attached monitoring data.)

Table VIII provides a summary of the existing loadings and the reduction needed to meet the allowable loadings according to the TMDL to achieve the stated water quality criterion values. A comparison between Table VII and VIII indicates that while there are minor discrepancies in calculated loadings, which are probably due to incorporation of additional monitoring data in Table VII, in general, the calculated loads are comparable and the trends are similar. Both tables indicate that while there are sources of pollutant loading above 906-15 (BC6), the majority of the loading enters the stream between this point and BC2. Both also illustrate that the water quality improves downstream and that no major additional sources enter the stream. According to the information in the TMDL, approximately 59 lbs/day of iron, 29 lbs/day of manganese and 3 lbs/day of aluminum need to be eliminated from Blacks Creek in order to meet applicable water quality criteria. The BMPs, proposed in this restoration plan, seek to meet the needed load reductions in order to restore the entire main stem of Blacks Creek. As will be further discussed, successful treatment of the “McIntire” discharges (TB1) and the BC14, BC15, and BC16 discharges would significantly reduce the loadings at BC2. Even though prediction is tenuous, the treatment of the discharges coupled with the noted existing attenuation, may lead to the level of reduction indicated in the TMDL.

Table VIII. TMDL: Existing, Allowable, and Reduction Needed

Sample Point	Existing			Allowable			Reduction Needed			% Reduction		
	Fe	Mn	Al	Fe	Mn	Al	Fe	Mn	Al	Fe	Mn	Al
BC6 [906-15]	0.6	3.5	2.8	0.6	0.7	0.2	0.0	2.8	2.6	0	79	92
BC2	60.2	26.6	1.8	1.2	1.1	1.0	59.0	22.8	0.4	98	96	29
BC2B	33.6	25.8	5.2	4.7	2.6	2.3	0.0	0.0	0.0	0	0	0
BC1	20.1	35.9	6.2	5.6	7.2	6.2	0.0	3.2	0.0	0	31	0
BC8	10.2	25.1	0.0	10.2	8.0	0.0	0.0	0.0	0.0	0	0	0

Loadings in lbs/day; all loading data reorganized from 2004 TMDL Table 3; based on data available during the period of study for the TMDL; BC6 in the TMDL is approximately the same sample point as 906-15 in the restoration plan.

Sedimentation

The poor water quality, accumulation of sediment from upgradient erosion, and precipitation and settling of metal solids appear to greatly impact the aquatic ecosystem in Blacks Creek. In addition, as the majority of Blacks Creek has a low or very low gradient (less than 2%), even as the water quality improves, the pre-existing metal precipitates in the substrate may not be flushed as readily as a stream with a higher gradient. According to the Slippery Rock Creek Watershed Assessment and Restoration Plan (Beran et al, 2006):

“Marginal habitat conditions are reflected in the relatively low median scores (range of 8 – 10.5) for sediment deposition in all the assessed streams. This indicates that sediment is degrading habitat with major deposition of fines (sand, silt, clay) in pools and glides reducing pool depth. Coarse sand and gravel deposition on bars, transverse riffles, and formation of sand deposits occur at obstructions frequently limiting habitat quality.”

Investigation of the sedimentation problem was not the focus of this report and requires further study for evaluation. Nonetheless, implementation of passive systems to collect metal sludge is expected to significantly assist in ameliorating the sediment problem in the stream.

Discussion of Mine Discharge Water Quality

The primary source of impairment to the watershed identified in the Blacks Creek TMDL was metals from abandoned mine drainage. Other sources may be on-lot septic systems; sedimentation from the erosion of stream banks, poorly-vegetated lands, and dirt/gravel roads; as well as nutrients and pesticides from agriculture. Investigation of these potential sources was beyond the scope of this report. Over 20 abandoned mine discharges exhibiting significant degradation and flow have been identified in the Blacks Creek Watershed. Numerous other small seeps exist. In addition, ephemeral, intermittent or other discharges of significance may exist within the watershed but remain unidentified.

Several abandoned mine discharges have been monitored for over 10 years while others have only recently been identified and monitored. Table IX provides a general characterization of these abandoned mine discharges. The water quality varies from alkaline water with relatively low metal concentrations to very acidic water with high metal concentrations. Unreclaimed surface mines on the Brookville coalbed, which characteristically encountered potentially alkalinity-generating material in the overburden, appear to have minimal impact to the water quality, other than possibly sedimentation. The only exception may be discharges 906-4 and 906-5 which emanate at the toe of an unreclaimed surface mine; however, it is unclear as to whether the source of the degradation is from a surface or an underground mine or both. Surface mining of coalbeds which included disposal of coal refuse and which did not encounter

substantial alkalinity-generating material in the overburden prior to implementation of modern, environmentally-based mining methods appears to have been the major contributor to stream degradation. These discharges shall be further discussed in the Restoration Plan section.

Table IX. Mine Drainage Water Quality Characteristics

Sample Point	Flow	pH field	Alkalinity		Acidity	Iron		Manganese		Aluminum		SO ₄

Flow in gallons/minute (gpm); pH in standard units; Alkalinity, acidity, total metals, dissolved metals, and sulfates in mg/L; Metals and pH rounded to nearest tenth; Alkalinity, acidity, and sulfates rounded to nearest whole number

Loadings were also calculated for each of the discharges and are presented in Table X. Since metals are the primary source of impairment to the watershed, the discharges were ranked based on total metal loadings. This ranking system was also used to help prioritize the restoration effort. Note that the top 3 discharges account for 64% of the metal loadings in the watershed while the top 5 account for 77% of the metal loadings. In contrast, the bottom 10 discharges account for only 7.5% of the metal loadings to the watershed.

Table X. Individual Mine Discharges Ranked by Total Metals Loadings

Rank	Point	Alkalinity	Acidity	Total Fe	Total Mn	Total Al	Total Fe, Mn, Al	% of Total Contribution

RESTORATION PLAN

In order to meet the TMDL criteria provided for Blacks Creek as well as achieve the ultimate goal of returning the stream to a viable fishery, a restoration plan has been developed. This plan proposes to passively treat the abandoned mine discharges that cause substantial degradation to Blacks Creek. The discharges have been grouped based on location and similar water quality. **The final effluent from the passive systems, as proposed, is expected to be characterized as net alkaline with low dissolved metals.**

Passive systems have been proposed to treat the significant sources of AMD degradation to Blacks Creek. In addition to describing the conceptual BMP, an estimate of the cost and pollutant loading reduction have been provided. Costing generally follows guidelines used in the *AMDTreat* software program (US OSM et al, 2006). Component selection and sizing are generally based on information provided in the US Department of Energy, National Energy Technology Laboratory report, "The Passive Treatment of Coal Mine Drainage" (Watzlaf et al, 2004). Development of the conceptual design as well as the estimated costs and pollutant loading reductions are also based on the experience of the BioMost, Inc. and Stream Restoration Inc. team that have designed and built over 200 passive components for over 35 systems, which successfully treat ~1 billion gallons of mine drainage annually.

While sophisticated modeling programs could be developed to predict pollutant loading reductions, experience has shown that pre- and post- construction water monitoring data often illustrate that undetected mine drainage such as shallow subsurface flow is commonly

encountered and treated by the system, typically resulting in higher pollutant loading removal than indicated by pre-construction monitoring. Nonetheless, a preliminary pollutant load reduction estimate is provided for each proposed passive system based only on existing pollutant loading of the discharge. Although passive systems have been online in the Slippery Rock Creek Watershed that have operated for more than a decade and have met or exceeded the design effluent criteria, typically passive systems are not expected to remove 100% of all pollutant loadings 100% of the time. Table XI briefly describes the functions of the components included in the passive treatment systems proposed for the Blacks Creek Watershed:

Table XI. Passive Treatment System Components: General Function and Description

Component	Function & Description
Step Aerator (SA)	Oxygenate AMD, convert Fe ⁺² to Fe ⁺³ , degas CO ₂ ; constructed of stainless-steel or other corrosive-resistant material
Oxidation & Precipitation Channel (OPC)	Promote removal and recovery of iron minerals at low pH; substrate limestone aggregate with geotextile
Vertical Flow Pond - oxic [VFP(oxic)]	Generate alkalinity; limestone aggregate; metal solids flushed automatically or manually
Vertical Flow Pond - anaerobic [VFP(anaerobic)]	Generate alkalinity; organic material with or without limestone aggregate; metal sulfides formed/retained; iron reduced (Fe ⁺³ to Fe ⁺²)
Settling Pond (SP)	Oxidize, precipitate, settle, retain metal solids
Aerobic Wetland (WL)	Oxidize, precipitate, settle, retain metal solids; provide wildlife habitat
Horizontal Flow Limestone Bed (HFLB)	Generate alkalinity; promote removal and recovery of manganese

Note: The descriptions and functions are applicable for this report only.

Unnamed “McIntire” Tributary #15 [includes discussion of TB1(MC1, MC2, MC3) and BC16]

The single largest impact to Blacks Creek is the “McIntire” trib #15, impacted by two discharges (TB1 & BC16) with the highest metal loadings (~50%) in the Blacks Creek Watershed. As noted previously, TB1 is the effluent of an existing old chemical treatment pond which receives three discharges (MC1, MC2, MC3) from the H&D “McIntire” minesite in the headwaters of trib #15. The TB1 primary spillway has become plugged with iron minerals precipitating at low pH to the point that the water now discharges over the emergency spillway, forming trib #15. (See photos.) Trib #15 is conveyed in a reconstructed stream channel to an in-stream settling pond (SB1). The SB1 effluent (trib. 15) confluences with BC16 just prior to entering Blacks Creek.

Table XII illustrates the water quality of trib #15 from the TB1 effluent to the confluence with Blacks Creek. (Samples are arranged from upstream to downstream.) Table XII also includes sample points on Blacks Creek upstream (906-42) and downstream (BC2) of the confluence with the “McIntire trib”. TRX, RS1, and RS2 are intermediate stream points between TB1 and SB1. These points illustrate the natural improvement in water quality both from dilution and from precipitation of iron minerals at a low pH. BC4.1 is the furthest downstream sample point below TB1 prior to BC16 entering the tributary. BC4 is on trib #15 directly downstream of the BC16 discharge and just upstream of the confluence with Blacks Creek. The impact of BC16 to trib #15 is quite remarkable. Based on the sample analyses, the iron content in trib #15 significantly increases while the aluminum content actually decreases. The alkaline BC16 discharge with an average flow rate of 74 gpm decreases the aluminum content in trib #15 both by dilution and by increasing the pH. (As aluminum solubility is controlled primarily by pH, once the pH reaches ~4.0 aluminum solids begin to form and by pH of ~5 only ~1 mg/L dissolved aluminum is typically in solution.) The impact of the “McIntire trib” to Blacks Creek is devastating as illustrated by comparing upstream (906-42) and downstream (BC2) points on Blacks Creek, with iron, manganese, and aluminum content doubling and in some cases tripling.

Table XII. Unnamed Tributary #15 Water Quality Data (Average Values)

Location	Sample Point	pH field	Alkalinity		Acidity	Iron		Manganese		Aluminum		SO ₄

Alkalinity, acidity, total & dissolved metals, and sulfates in mg/L; Metals and pH rounded to nearest tenth; Alkalinity acidity, and sulfates rounded to nearest whole number; Number of sample sets (n) varies. (See attached monitoring data.)

“McIntire” Site TB1 (MC1, MC2, and MC3): The “McIntire” bond forfeiture surface mine and coal refuse disposal site has the single largest impact to the Blacks Creek Watershed. A terrain conductivity study was completed by the PA DEP to identify “hot spots” at the minesite. This information was used to determine placement of alkaline material at the site. In 2006, local limestone quarry operator and active Slippery Rock Watershed Coalition participant, Quality Aggregates Inc., placed approximately 10,000 tons of waste lime to create a low-permeability barrier and to provide alkalinity to the subsurface flow. Long-term improvement will be demonstrated by monitoring site drainage. Based on experience with similar efforts, loadings are expected to decrease but degradation is expected to remain. A passive system, therefore, that has the capability of handling differing site drainage characteristics is proposed.

Proposed Passive Treatment System Components

“McIntire” Mine Site (TB1)

SA → OPC → VFP(oxic) → OPC → SP(existing) → VFP(anaerobic) → SP/WL(0.5 ac) → HFLB

Treatment Media: VFP(oxic)-1500 tons limestone; VFP(anaerobic)-3100 tons limestone, 1200 CY compost, 1200 CY wood chips; HFLB-1500 tons limestone

Projected Decrease in Pollutant Loadings:
 (~82,000 lbs/yr acidity; ~32,000 lbs/yr metals)

Parameter	Acidity	Iron	Manganese	Aluminum
Lbs/day	~226	~64	~17	~8

Preliminary Cost Estimate: ~\$600,000

BC16: The BC16 discharge, which emanates from an old oil well, has the second highest metal loading in the watershed. While the final design has not yet been completed, Stream Restoration Incorporated has received a \$151,740 PADEP/EPA 319 grant to construct a 2/3- to 1-acre aerobic wetland for the oxidation, precipitation, and settling of iron and a 1,500-ton, Horizontal Flow Limestone Bed for manganese removal and alkalinity generation. Successful completion of the BC16 passive treatment system is expected to neutralize 7 lbs/day of acidity and remove 49 lbs/day of iron and 15 lbs/day of manganese. This equates to a load reduction from the discharge of 2,600 lbs/year of acidity and 41,000 lbs/year of metals.

Based on available data, completion of the “McIntire” and BC16 passive treatment systems are expected to eliminate roughly 50% of the total metal loadings, including 60% of the iron and 45% of the manganese to Blacks Creek. The elimination of this pollution source is expected to significantly improve the water quality of Blacks Creek.

BC14 & BC15

BC14 and BC15 are ranked 10th and 3rd, respectively, in terms of total metal loadings to Blacks Creek. Because of the proximity to one another, the discharges would most likely be treated in one passive system. Like BC16, the discharges appear to emanate as upwellings from old abandoned oil wells. BC14 & BC15 can be characterized as alkaline, net-acidic, iron- and manganese-bearing discharges with low aluminum content. Both discharges flow directly into Blacks Creek.

The data available for BC14 is quite variable. Interestingly, the sample dates with flow measurements all have extremely low iron concentrations while samples with no flow measurements have rather high iron concentrations. Likewise two of the dates with flow measurements have much lower manganese concentrations. This discrepancy makes developing a design and predicting results difficult. Also, this may cause BC14 to be ranked lower on the priority list. While a conceptual design has been developed, additional monitoring will be necessary prior to completing a final design.

Proposed Passive Treatment System Components

BC14 & BC15

SA → WL(1.5 ac) → HFLB

Treatment Media: HFLB-2,000 tons limestone

Projected Decrease in Pollutant Loadings:
 (~1,800 lbs/yr acidity; ~16,000 lbs/yr metals)

Parameter	Acidity	Iron	Manganese	Aluminum
Lbs/day	~5	~35	~10	Na

Estimates tenuous due to variable water quality reported.

Preliminary Cost Estimate: ~\$300,000

BC19 & BC19B

The BC19 & BC19B discharges are ranked 9th and 6th, respectively, in terms of metal loadings. These discharges which formerly flowed directly into Blacks Creek are currently being treated by a ~½-acre aerobic wetland that was constructed in 2004 with grant funding of about \$110,000. Additional monitoring is needed to evaluate seasonal changes in water quality related to vegetation and ice cover. On average, ~12 lbs/day (~4,300 lbs/yr) of iron is being removed. (Additional monitoring is needed to confirm the apparent removal of 1 lb/day of manganese.)

906-7, -8, and -9

Abandoned mine discharges 906-7, -8, and -9 are ranked 16th, 4th, and 15th, respectively, in terms of metal loadings to Blacks Creek. Due to numerous subsidence features in the general vicinity of the 906-8 and -9 discharges, the source of the drainage is believed to be from an abandoned underground mine. Discharge 906-7 is an upwelling from an old oil well. Because of the proximity to one another, the discharges have been grouped into one passive treatment system design. These discharges do not appear to have been previously sampled at their source. The combined discharges may be reflected in PA DEP sampling point BC17. As only one sampling event was conducted, prior to finalizing the design, additional sampling and site investigations are recommended. Depending upon the final design and actual construction conditions, including the 906-7 discharge may not be feasible. The following conceptual design and estimated cost are based on one sample set. Due to the limited data, the system was designed using the water quality data for the most degraded discharge (906-8) coupled with the combined total flow of all three discharges. This conservative approach helps to ensure that the size and cost of the passive system are not underestimated. Again, further investigations should be completed prior to finalizing the design.

Proposed Passive Treatment System Components

906-7, 906-8, 906-9

SA → OPC(length 500') → VFP(oxic) → OPC (length 500') → SP/WL(0.5 ac) → VFP(anaerobic) → SP/WL(0.5 ac) → HFLB

Treatment Media: VFP(oxic)-1000 tons limestone; VFP(anaerobic)-2000 tons limestone, 800 CY compost, 800 CY wood chips; HFLB-1000 tons limestone

Projected Decrease in Pollutant Loadings:
 (~34,000 lbs/yr acidity; ~9,000 lbs/yr metals)

Parameter	Acidity	Iron	Manganese	Aluminum
Lbs/day	~95	~13	~3	~9

Preliminary Cost Estimate: ~\$500,000

906-17 (includes discussion of 906-16 and 906-17B)

Mine discharge 906-17, ranked 7th, flows across a reclaimed surface mine site where the discharges mix with relatively good quality surface runoff prior to entering an old sediment pond. The effluent of the sediment pond (906-16) is the headwaters of tributary #16. A smaller discharge, 906-17B, is located ~20 feet from 906-17 and was not sampled, although pH, ORP, and flow were measured. Because of the proximity to 906-17, 906-17B has been assumed to be of similar quality. (Additional sampling is necessary to confirm this assumption.) As can be seen from Table X, the loadings for the sediment pond effluent (906-16) and for the abandoned mine drainage (906-17) are rather similar, even though 906-16 has slightly higher metal loadings while 906-17 has higher acidity loadings. While an extensive search was not completed, there appears to be no available historic data for these sampling points. Even though the final location of the passive treatment system has not been determined, for the purpose of this restoration plan, the proposed location is upgradient of the settling pond so as to only intercept and treat the mine drainage. This has significantly reduced the size and cost of the passive system as many of the components are designed based upon flow rate, retention time, and water quality. (A higher flow rate with approximately the same loading may require a larger system because of the retention time needed.) The proposed system was based on only one sample event. Further water monitoring will be needed prior to finalizing system design.

Proposed Passive Treatment System Components

906-17 & 906-17B (hydrologically related to 906-16)

VFP(anaerobic) → SP/WL(0.5 ac) → HFLB

Treatment Media: VFP(anaerobic)-1800 tons limestone, 700 CY compost, 700 CY wood chips;
 HFLB-1000 tons limestone

Projected Decrease in Pollutant Loadings:
 (~27,000 lbs/yr acidity; ~4,000 lbs/yr metals)

Parameter	Acidity	Iron	Manganese	Aluminum
Lbs/day	~74	<1	~3	~9

Preliminary Cost Estimate: ~\$300,000

906-4 & 906-5

The 906-4 and 906-5 abandoned mine discharges are ranked 8th and 13th, respectively, in terms of metal loadings. These discharges mix with mine discharges 906-7, -8, -9 and other smaller seeps as well as some sources of good quality water and essentially form the headwaters of Blacks Creek. These discharges are the primary source of impairment within the watershed until the stream reaches the oil well upwellings of BC14 and BC15 and the “McIntire” tributary. Addressing discharges 906-4 and 906-5 will be necessary for the entire Blacks Creek to meet water quality criteria. The origin is uncertain as to whether the source of these discharges is an abandoned underground mine or an unreclaimed surface mine or both. Further investigation is necessary to determine if land reclamation either alone or in combination with a passive treatment system is necessary to improve the drainage. These discharges do not appear to

have been previously sampled. While a conceptual design has been provided, as only one sample set is available, additional monitoring is necessary prior to completing a final design.

Proposed Passive Treatment System Components

906-4 & 906-5

OPC(2 channels) → VFP(anaerobic) → SP/WL(0.5 ac) → HFLB

Treatment Media: VFP(anaerobic)-2000 tons limestone, 800 CY compost, 800 CY wood chips;
 HFLB-600 tons limestone

Projected Decrease in Pollutant Loadings:
 (~34,000 lbs/yr acidity; ~5,000 lbs/yr metals)

Parameter	Acidity	Iron	Manganese	Aluminum
Lbs/day	~95	<1	~3	~10

Preliminary Cost Estimate: ~\$300,000

906-36

The 906-36 discharge, ranked 11th in terms of metal loadings, is assumed to be an upwelling from an old oil well. Historical data for this discharge does not appear to exist. Based on the one available sample analysis, the impact to Blacks Creek is minimal as the discharge is net alkaline and only contributes ~4 lbs/day of iron. The restoration effort for this discharge, therefore, is low on the priority list. Nonetheless, a conceptual design and cost estimate have been developed which consists of ~1/4-acre aerobic wetland. Additional water monitoring will be necessary prior to finalizing the design. The project has been estimated to cost ~ \$100,000.

906-21

The 906-21 discharge is ranked 12th in terms of metal loadings. The exact source of the discharge is not known, but it emanates along tributary #7 just prior to the confluence with tributary #6. The discharge has limited impact to the stream and is, therefore, low on the priority list. Additional water monitoring will be necessary prior to finalizing the design. A ~1/4-acre aerobic wetland is proposed which would remove ~4 lbs/day of iron. The project has been estimated to cost ~\$100,000.

906-14

The 906-14 discharge is ranked 14th in terms of metal loadings. It emanates along County Line Road and is conveyed in a ditch through a road culvert and into a natural wetland prior to entering tributary #17. The discharge has limited, if any, impact to the stream as most of the iron precipitates within the road ditch and natural wetland. The discharge has a loading of ~1.5 lbs/day of iron and 0.5 lbs/day of manganese. A 0.1-acre wetland would probably be sufficient to remove the remaining iron. To remove the manganese, 100 tons of limestone would be needed. The cost has been estimated at ~\$50,000. As there is little or no impact from discharge 906-14, implementation of treatment is not proposed.

906-22 & 906-23

Abandoned mine discharges 906-22 and 906-23 are ranked 17th and 19th in terms of metal loadings, contributing ~1 lb/day. As these two discharges form tributary #7, installation of a small passive system consisting of a ~0.1-acre wetland would improve at least a short segment of the tributary; however, because of other sources of good quality water, tributary #7 improves rapidly. These discharges, therefore, would be placed low on the priority list. The estimated cost is ~\$50,000.

906-24

Sampling point 906-24 is the effluent of a settling pond on a reclaimed surface mine receiving primarily surface run-off. The discharge of this settling pond forms tributary #6. There does not appear to be any historic data available for this site. At this sampling point, while the effluent does meet surface mining water quality standards, 906-24 does not meet the applicable water quality criteria. As better quality waters are encountered, 906-24 improves substantially as evidenced by sampling point 906-27. Like many of these smaller discharges, a small 0.1-acre wetland could be installed; however, due to the lack of known impact, a passive system is not currently recommended.

PRIORITIZATION, SCHEDULING, EVALUATION, and COST ESTIMATE SUMMARY

As obtaining landowner support (except for the “McIntire” site for which Stream Restoration Inc. has a written support letter) and as determining construction site suitability are beyond the scope of this report, pollutant loadings and estimated impacts to the streams were used to develop the priority list in Table XIII with cost estimates for proposed passive treatment systems. Implementation of all proposed passive systems is estimated to cost about \$2.6 million dollars. Potential sources of available funding to implement these projects are provided in Table XVI.

Table XIII. Summary of Priority List and Cost Estimates

Priority Ranking	Sample Point	Cost Estimate
(completed)	BC19 & BC19B	\$110,000
1	TB1 (“McIntire” Site)	\$600,000
2	BC16	\$150,000
3	BC14 & BC15	\$300,000
4	906-7,-8, -9	\$500,000
5	906-4, -5	\$300,000
6	906-17 (& 17B)	\$300,000
7	906-36	\$100,000
8	906-22, -23	\$50,000
9	906-21	\$100,000
10	906-14	\$50,000
11	906-24	NA
Total		\$2,560,000

Cost estimate provided for the BC19 & BC19B passive system does not include in-kind/matching contributions.

Tables XIV and XV provide estimated TMDL reductions for Blacks Creek at sample points BC6 and BC2 for seven out of the proposed eleven passive systems. In order to generally estimate

the impact of the seven proposed systems, certain assumptions were made. The first assumption is that the entire pollutant load of the mine discharge will be treated by the passive system. Second, while the decrease of loading due to apparent natural attenuation is provided in the tables, apparent natural attenuation was not considered in estimating the pollutant loading contributions of each discharge. (In this case, apparent natural attenuation is attributed to unaccounted surface and subsurface flow and to the chemical, physical, and biological processes that occur within the streams resulting in the precipitation and settling of metals from the water column.) A third assumption is that the available data is accurate and representative of typical water quality and flow conditions.

The remaining four proposed passive systems (addressing discharges 906-21, -22, -23, -24, and -36) were not included in Tables XIV and XV as implementation is downstream of BC6 and BC2 and would, therefore, have no impact to the segments of Blacks Creek identified for TMDL pollutant loading reductions. Note that TMDL reductions are improvements needed to the main branch of Blacks Creek at specific sampling point locations and not improvements to the individual tributaries for restoration of the entire watershed.

**Table XIV. Blacks Creek Point BC6 TMDL:
 Discharge Contribution and Corresponding Passive System Reduction (prelim. est.)**

Sample Point	Pollutant Loading by Source (lbs/day)				Percentage of Total Source Load by Discharge				Estimated Load Contribution (Reduction) to point BC6			
	Fe	Mn	Al	Acidity	Fe	Mn	Al	Acidity	Fe	Mn	Al	Acidity
906-7,8,9	12.7	3.3	9.0	95.2	95%	51%	46%	50%	0.6	1.8	1.3	7.3
906-4,5	0.6	3.2	10.6	94.8	5%	49%	54%	50%	0.0	1.7	1.5	7.3
Apparent Natural Attenuation	-12.7	-3.0	-16.8	-175.4								
BC6	0.6	3.5	2.8	14.6	100%	100%	100%	100%	0.6	3.5	2.8	14.6

Pollutant discharge loadings (n varies) from existing data provided in appendix; BC6 loading from Final Blacks Creek TMDL Table 3 - Summary...; assumes 100% discharge load reduction with installation of passive system; apparent natural attenuation attempts to quantify pollutant loading reduction from chemical, physical, and biological processes; BC6 loading attributed to discharges (percentage and quantity) does not consider natural attenuation in Blacks Creek; Estimated Load Contribution (Reduction) to point BC6 is calculated by multiplying BC6 loading (bottom row first column set) by the Percentage of Total Source Load by Discharge for each pollutant.

**Table XV. Blacks Creek Point BC2 TMDL:
 Discharge Contribution and Corresponding Passive System Reduction (prelim. est.)**

Sample Point	Pollutant Loading by Source (lbs/day)				Percentage of Total Source Load by Discharge				Estimated Load Contribution (Reduction) to point BC2			
	Fe	Mn	Al	Acidity	Fe	Mn	Al	Acidity	Fe	Mn	Al	Acidity
BC6	0.6	3.5	2.8	14.6	0%	6%	14%	4%	0.2	1.7	0.6	0.0
906-14	1.6	0.5	0.0	0.8	1%	1%	0%	0%	0.6	0.2	0.0	0.0
906-17/17B	0.1	3.4	8.7	73.6	0%	6%	44%	22%	0.0	1.7	1.7	0.0
BC14/BC15	34.8	15.1	0.2	11.9	23%	28%	1%	4%	13.9	7.5	0.0	0.0
TB1	64.0	16.7	8.1	225.5	43%	31%	41%	68%	25.6	8.2	1.6	0.0
BC16	49.2	14.7	0.2	7.2	33%	27%	1%	2%	19.7	7.3	0.0	0.0
Apparent Natural Attenuation	-90.1	-27.3	-16.0	-333.6								
BC2	60.2	26.6	4.0	0.0	100%	100%	100%	100%	60.2	26.6	4.0	0.0

(See notes for Table XIV.) BC6 and BC2 loadings from Final Blacks Creek TMDL Table 3 - Summary...; BC2 loadings attributed to discharges (percentage and quantity) does not consider apparent natural attenuation in Blacks Creek; implementation of proposed passive systems at 906-7,8,9 and 906-4,5 upstream of BC6 expected to result in loading reductions at BC2 of 0.2 lbs/day, 1.7 lbs/day, 0.6 lbs/day, 0.0 lbs/day of Fe, Mn, Al, acidity, respectively; Estimated Load Contribution (Reduction) to point BC2 is calculated by multiplying BC2 loading (bottom row first column set) by the Percentage of Total Source Load by Discharge for each pollutant.

Table XVI. Potential Funding Sources for Implementing Blacks Creek Restoration Plan

Funding Source	Contact Information	Eligible Uses	Amount
PA DEP Growing Greener Program	PA DEP Grants Center RCSOB, 15th Floor 400 Market Street P.O. Box 8776 Harrisburg, PA 17105 717-705-5400 www.depweb.state.pa.us	Watershed restoration implementation (construction) projects, O&M, education/outreach projects, watershed organization, and watershed assessment	No known maximum or minimum
US EPA Section 319 Nonpoint Source Program	PA DEP Grants Center RCSOB, 15th Floor 400 Market Street P.O. Box 8776 Harrisburg, PA 17105 717-705-5400 www.depweb.state.pa.us	Projects addressing nonpoint sources including AMD restoration (construction projects); watersheds with approved TMDLs and restoration plans considered a priority	No known maximum or minimum
US OSM Appalachian Clean Streams Initiative	US OSM Harrisburg Field Office 415 Market Street, Suite 3 Harrisburg, PA 17101 717-782-2285	AMD restoration (construction projects) in the Appalachian Region	Up to around \$100,000 with no defined maximum
Western Pennsylvania Watershed Program	John Dawes RR#1, Box 152 Alexandria, PA 16611 814-669-4847 www.wpawp.org	Watershed restoration and preservation projects including AMD	No known min/max; funding typically ≤\$20,000/ project
Dominion Foundation	Pennsylvania Community Investment Board Attn: Ms. Anita M. Wilson Dominion Peoples 625 Liberty Avenue Pittsburgh, PA 15222 http://www.dom.com/about/community/foundation	Projects that preserve, protect, and improve the quality of the environment in communities Dominion companies operate	\$1,000 to \$15,000
Common Grant Application	Grant Makers of Western Pennsylvania 650 Smithfield St., Suite 210 Pittsburgh, PA 15222 412-471-6488	Variety of uses; application may be used for many different foundations, although each foundation should be contacted individually	Varies

Table XVII provides a proposed time table for implementing the restoration plan. Design and construction of the BC16 passive treatment system are expected to be completed in 2007. Seeking funding for the “McIntire” site will begin in 2007 as well. Following completion of these two passive systems, an evaluation of the impact to Blacks Creek will be conducted. Priorities may be rearranged following this evaluation. After completion of each additional major project, another evaluation is recommended to be completed in order to restore Blacks Creek in the most efficient and economical manner possible. Load reductions and the water quality criteria are to be used, primarily, for evaluating the progress of the restoration plan. This priority list and proposed time table are to serve as a guide to developing implementation projects within the Blacks Creek Watershed. The priority list and proposed time table are to be revised as needed.

Table XVII. Proposed Time Table for Implementing Restoration Plan

Passive System	Obtain Funding		Design & Construct	
	Start	End	Start	End
BC19 & BC19B	Completed		Completed	
BC16	Completed		1/2007	12/2007
“McIntire”	1/2007	3/2008	3/2008	12/2008
BC14 & BC15	1/2008	3/2009	3/2009	12/2009
906-7,-8, -9	1/2009	3/2010	3/2010	12/2010
906-4, -5	1/2010	3/2011	3/2011	12/2011
906-17 (& 17B)	1/2011	3/2012	3/2012	12/2012

WATER QUALITY MILESTONES AND PROGRESS EVALUATION

Water quality milestones will be used to evaluate the progress and degree of success in the implementation of the restoration plan, as the primary purpose of this plan is to improve the water quality of Blacks Creek and its tributaries with the ultimate goal of returning the stream to a viable fishery. Water monitoring shall be conducted by SRWC partners, which includes, but is not limited to PA DEP, Stream Restoration Inc., volunteers, etc. When funding is available water samples will be collected and analyzed by a laboratory for standard mining parameters including pH, alkalinity, acidity, iron, manganese, aluminum, sulfates, and suspended solids. When funding is not available for laboratory analyses field kits may be used to measure pH, alkalinity, and iron. Ideally, flow rate is also to be measured. At a minimum, water monitoring should be conducted twice a year although quarterly is preferred at sampling points 906-15, BC2, BC2B, BC1, and BC8. Monitoring locations are proposed at the influent and effluent for each passive treatment system as well as on the receiving stream above and below the confluence with the final system effluent. [monitoring to follow EPA-approved QAPP (BioMost et al, 2006)]

Once per year, the SRWC will review available water quality data related to Blacks Creek and discuss the progress of the implementation plan. This will most likely be conducted during one of the monthly public meetings during the 1st quarter of the year. With each new passive treatment system installed, the degree of improvement to the impacted tributary and/or main branch of Blacks Creek will be reported. In general, these improvements are expected to be reflected by increases in pH and alkalinity values and decreases in acidity, iron, manganese, and aluminum values. Implementation of the restoration plan, as feasible, shall continue until applicable water quality criteria have been met.

PUBLIC PARTICIPATION

Public participation in the restoration plans and project implementation has always been encouraged by the SRWC and Stream Restoration Inc. Progress relating to plan development has been discussed at the SRWC monthly meetings (open to the public) as well as outreach events. As this plan outlines the restoration of an entire watershed, the major stakeholders includes everyone who lives within the watershed, especially the landowners who have property directly impacted by abandoned mine lands, people who use the watershed recreationally, those who work in the watershed, the SRWC, and the PADEP. The SRWC, Stream Restoration Inc., and PA DEP will be leading the effort to implement the plan. In order to inform the public about the progress of implementing the plan, various education/outreach activities will be utilized including the internet, our monthly newsletter *The Catalyst*, newspaper articles, monthly SRWC meetings and public outreach events such as the annual July 4th Harrisville Community Day. The plan may be uploaded to either the SRWC (www.srwc.org) or Stream Restoration Inc. (www.streamrestorationinc.org) websites. Water monitoring data will be uploaded to the on-line GIS and database management website Datashed www.datashed.org.

CONCLUSIONS

The watershed of Blacks Creek, a major headwaters tributary to Slippery Rock Creek, has been extensively mined through both surface and underground methods. In addition, the northern portion of the watershed was developed for oil production. These extensive resource extraction activities have severely degraded portions of the watershed. In addition to the TMDL developed by the PADEP Knox District Mining Office in 2002, a restoration plan has now been developed by BioMost, Inc., Stream Restoration Inc., and the SRWC based upon available data compiled from a variety of sources as well as newly acquired water quality data obtained while conducting stream walks of the watershed. This restoration plan has described all observed major sources of mine drainage that impact the Blacks Creek Watershed. Conceptual passive treatment Best Management Practices (BMPs) have been developed and cost estimates provided for these major sources of mine drainage. The restoration projects were then prioritized and a proposed time table for implementation was developed. In some cases, due to limited available data, additional water monitoring of mine discharges and more thorough site investigations will be required prior to finalizing the proposed passive treatment system designs. Occasional re-evaluations of the watershed to determine the progress of the restoration effort and possible reprioritization of the mine drainage abatement projects will be necessary to ensure a wise use of available funding and resources in order to restore the watershed in the most efficient, economical, and environmentally-friendly manner as feasible.

AMD discharges 906-4 (Left) and 906-5 (Center) as well as other seeps (Right) and good quality sources of water form unnamed tributary #18, which feeds into the large AMD impacted wetland complex.

Illegal dumps (Left), highwalls (Left), and water-filled pits (Center and Right) are located throughout the watershed.

AMD discharges 906-8 (Left) and 906-9 (Right) emanate from an abandoned underground mine evidenced by numerous subsidence features (Center) present in the vicinity. These discharges are collected by a beaver dam.

AMD discharges 906-7,-8,-9 mix with good quality water in a beaver dam wetland (Left) before entering the larger AMD impacted wetland complex (Center) with the outlet forming Blacks Creek (Right).

Wetlands/springs like 906-1(Left) are sources of good quality water to the watershed. 906-1 mixes with unnamed tributary #19 (Center), which raises the pH to precipitate aluminum (Center and Right) within the stream.

AMD discharge 906-14 (Left), along County Line Road, has minimal impact to good quality tributary #17 which confluent with Blacks Creek at 906-15 (Center)...Sediment Pond 906-16 (Right), at the headwaters of tributary #16 receives surface runoff from a reclaimed strip mine and AMD discharges 906-17, -17B.

Historic oil wells (Left), piping systems, and storage tanks (Center) can be seen throughout the northern portion of the watershed. These old oil wells can provide a conduit for mine drainage to reach the surface. Discharges BC14 and BC15 severely impact Blacks Creek as can be seen downstream at sampling point 906-42 (Right).

Existing treatment pond TB1 (Left) receives mine discharges MC1, MC2, and MC3 which emanate from the "McIntire" site. The effluent of TB1 (Right) forms tributary #15. The natural formation of iron minerals at low pH, plugging old piping (Center), is to be utilized and enhanced as part of the proposed passive system.

The BC16 discharge upwelling (Left) from an old oil well is the 2nd largest source of metal loadings in the watershed and flows into tributary #15 (Center & Right). A passive system is to be constructed in 2007.

Discharges BC19 & 19B (Left) are upwellings from old oil wells, which use to flow directly into Blacks Creek, but are now captured and treated in a passive treatment wetland (Right). Blacks Creek sampling point BC2B (Center) is downstream of all known major AMD discharges. Note the historic oil pipeline crossing Blacks Creek.

Several working farms, such as this one (Left) located downstream of BC2B, use the water resources within the watershed. Even though good quality streams such as tributary #14 (Center) improve Blacks Creek significantly it remains impacted at sampling point BC1 (Right) by sedimentation and metal loadings.

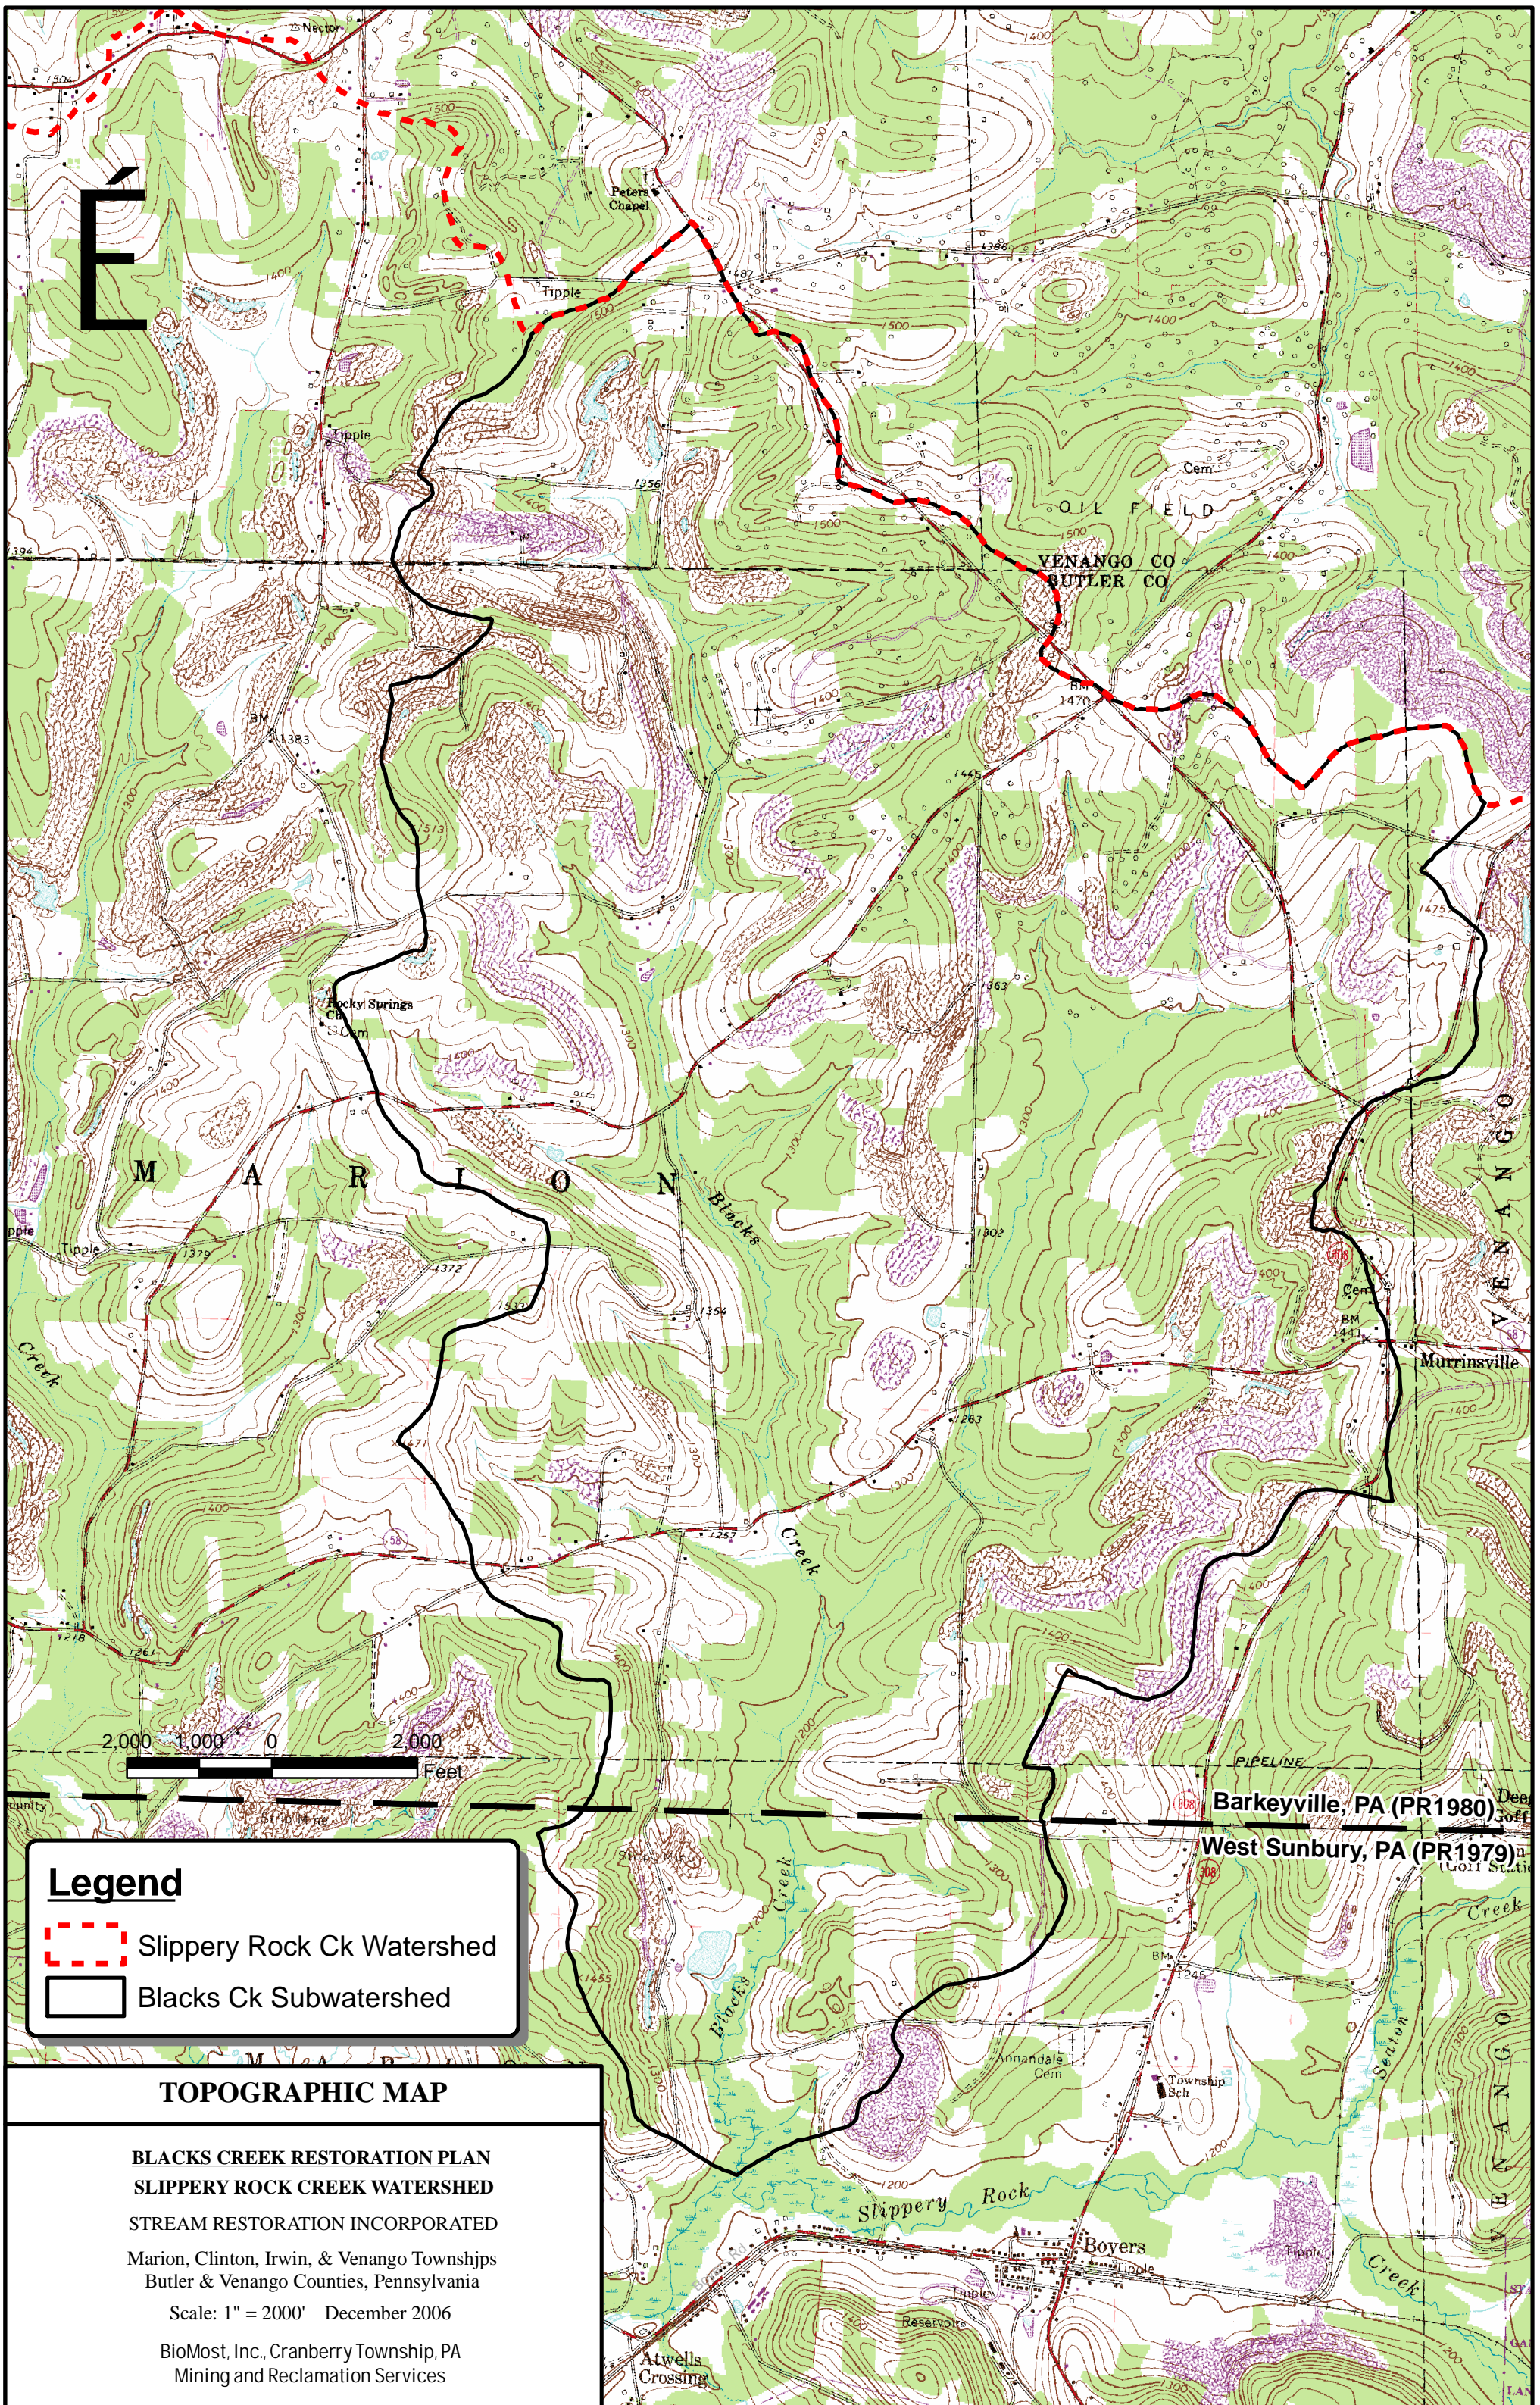

The oil well upwelling 906-36 (Left) has a minimal impact to Blacks Creek. An Allegheny Mineral limestone quarry (Center) has “eliminated” pre-existing AMD discharges. Blacks Creek remains slightly impacted at BC8 (Right).

Unnamed tributary #7 is formed by two small AMD discharges 906-22 and 906-23; however, the tributary quickly assimilates the drainage and becomes a stream with excellent water quality and habitat (Center). Another small AMD discharge 906-21 enters the stream just before the confluence with tributary #6. Other small seeps with little impact exist in the watershed like this on unnamed tributary #8 (Right).

Tributary #6 is essentially formed by the effluent of several old settling ponds (Left) that receive runoff from a large successfully reclaimed surface mine. The water quality meets mining effluent limits, but is slightly higher than the stream water quality criteria identified in the TMDL. The tributary quickly assimilates the drainage and is of excellent quality at sampling point BC12 (Center). Tributary #6 then confluences with and improves the water quality of Blacks Creek. The final downstream sampling point QAS4 (Right) on Blacks Creek is located below a Quality Aggregates limestone quarry.

Notes: Stream gradient created with AutoCAD Civil 3D utilizing streams digitized from aerial photography (1' resolution) and a digital terrain model (DTM) generated from USGS contours (20' interval). Grade breaks within the resulting profile were transferred to the plan view of the stream layer and imported to ArcGIS.

Digital elevation model based on National Elevation Dataset (NED) 1/3 Arc Second. Digital elevation model overlaid onto hillshade generated using ArcGIS 9.2 Spatial Analyst Extension.
